ture, which is controlled by platinum-platinorhodium thermocouple 3 and pyrometer 1. Metal container 8 is filled with the test composition, with cone valve 7 in closed position, and maintained at the fixed temperature for 30 min. Thereupon, the outflow time of the electrolyte is measured with the aid of a stopwatch. The electrolyte flowing out of container enters receiver 2 and may be re-used for additional tests. Findings: an increase in the percentile content of Na_2CO_3 considerably reduces electrolyte viscosity. For example a 5% increase in Na_2CO_3 concentration reduces the outflow time of the electrolyte by 1.5 times at 800°C. The dependence of electrolyte viscosity on Na_2CO_3 content is illustrated by Fig. 2, which shows that as the Na_2CO_3 concentration is increased to 30% the viscosity of electrolyte markedly decreases. This makes it possible to reduce boronizing temperature to 800-820°C. Thus, a desirable composition of electrolyte for electrochemical boronizing would be: 30% borax, 40% boric oxide, and 30% Na_2CO_3 . Orig. art. has: 3 figures.

TITLE: Automatic fluorescent x-ray spectrometer

SOURCE: Pribory i tekhnika eksperimenta, no. 3, 1966, 198-202

TOPIC TAGS: automatic spectrometer, x ray spectrometer

ABSTRACT: A newly developed all-wave vacuum fluorescent automatic x-ray spectrometer is briefly described; intended for both qualitative and quantitative analyses, the two-beam spectrometer permits programing of 24 lines. The programing unit has storages for these parameters: the Wulf-Bragg angle, discrimination threshold, discrimination-window width, standard or timer pulses, collimator type, sequence of interrogation of lines. These units are mentioned or described: x-ray optical system; primary and secondary collimators; crystal analysers (LiF and $\text{NH}_4\text{H}_2\text{PO}_4$); radiation detectors (proportional and $\text{NaI}(\text{Tl})$ scintillation counters); amplifiers, supply packs, etc. The BKhV-6 x-ray tube (50 kv, 100 ma) permits exciting the K-series of elements with $Z = 12-60$ and the L-series with $Z > 60$. Data regarding counting rates of pure elements is supplied.

Biochemical peculiarities in ripening and storage of green peas. I. I. Varentsov and V. M. Tsekhomskaya (Food Ind. Ministry, Moscow). *Biokhimiya Plodov i Ovoshchей*, Sbornik 2, 150-60(1051).—The d. of the pea as detd. with a penetrometer and the d. of the pea detd. pyknometrically can serve as ripeness indexes. Best quality material has a penetrometer index not over 2500, d. 1.02-1.04, high sugar content (av. 5%), and low ratio of starch/sugar. A product less desirable for canning that is overripe shows 3000 or more penetrometer reading, d. 1.04-1.06, 3-3.5% sugar, and up to 8% starch, or higher. Unshelled peas were stored 19 days at 0° without deterioration with a small rise of starch; shelled peas show a greater change of the starch/sugar ratio. Storage at -2° leads to bad flavor, caused by underoxidized substances. Storage at 8° leads to rapid decline of sugar and rise of starch and gives unsatisfactory results. A photograph of the penetrometer is given.

TITLE:

On the Arenaceous Devonian Rocks of the Tuva Depression and
Problems of Their Classification (O peschanykh porodakh de-
vona Tuvinskogo progiba i voprosakh ikh klassifikatsii)
Article 1 (Stat'ya 1)

PERIODICAL: Byulleten' Moskovskogo Obshchestva Ispytateley Prirody, Otdel
Geologicheskiy, 1957, No 3, pp 93-115 (USSR)

ABSTRACT:

General problems of classification and nomenclature of sandstones are considered in the article. In particular, an attempt is made to advance a detailed classificatory subdivision of complex multi-component arenaceous rocks of the Middle and Upper Paleozoic systems in the Tuva depression. The author proposes the following nomenclature:
1) Quartz sandstones are conventionally characterized by quartz content from 70 to 95%; feldspar, mica and other components up to 30%.
2) Feldspar-quartz sandstones may contain 75 to 100% of quartz, 10 to 25% of feldspar, and up to 15% of various detritus of fine-grained rocks.
3) Arkose sandstones or arkoses are composed of coarse grains of glassy quartz and feldspar mixed in unequal quantities and

Card 1/4

5-3-6/37

On the Arenaceous Devonian Rocks of the Tuva Depression and Problems of
Their Classification. Article 1

some admixtures of accidental substances, such as mica, clay,
etc.

4) Graywackes or graywacke sandstones, which in turn can be
subdivided into 3 subtypes:

a. Graywacke sandstones proper are characterized by the
quartz content of up to 50%, feldspars and mica up to 10%,
various detritus of fine-grained metamorphic rocks - not less
than 50%.

b. Feldspar-graywacke sandstones differ from graywackes
proper by a somewhat larger content of feldspars (from 10 to
25%) and corresponding changes in the content of other com-
ponents.

c. Quartz-graywacke sandstones are characterized by the
quartz content from 50 to 75%, feldspar content from 0 to
25%, and detritus of various fine-grained metamorphic and
sedimentary rocks from 25 to 50%. Most of the quartz-gray-
wacke arenaceous rocks of the Devonian system in Tuva contain
noticeable amounts of tuff breccia, and therefore these rocks
can be called tuffite quartz-graywacke sandstones.

Card 2/4

5-3-6/37

On the Arenaceous Devonian Rocks of the Tuva Depression and Problems of
Their Classification. Article 1

Tuffs contain no less than 80 to 90% of pyroclastic detritus of volcanic origin. Tuffogenous sandstones or tuffites contain from 50 to 80% of volcanic material. The content of arenaceous rocks is usually depicted graphically by means of triangular diagrams. The multi-component vector diagram composed by A.N. Zavaritskiy is the best one. It represents a rectangular tetrahedron shown on a plane. The author proposes some modifications of this diagram as applied to arenaceous rocks. Their main groups are as follows:

1. The unfolded rectangular tetrahedron is divided into 2 fields: left one for pyroclastic, volcanic rocks, and the right one for normal sedimentary, clastogene rocks;
2. The vertex of the right angle corresponds to the 100% quartz content. The lower tetrahedron vertex corresponds to the 100% content of fine-grained detritus of rocks, the right vertex corresponds to the 100% content of the sum of alkaline feldspars plus mica. These two components are closely interconnected petrogenetically. The left vertex corresponds to the 100% content of volcanic detritus. The sum of the

Card 3/4

5-3-6/37

On the Arenaceous Devonian Rocks of the Tuva Depression and Problems of
Their Classification. Article 1

so-called basic characteristics located in the vertices of
the rectangular tetrahedron amounts to 100%.

3. Additional characteristics, introduced for the more complete description of the real content, are expressed by means of vectors, whose scale is conventionally adopted as being 2.5 times as small as that of the basic characteristics of the diagram. The author gives some examples of applying his vector diagram for arenaceous rocks of the Tuva depression. The article contains 1 table, 10 diagrams and 59 references, of which 16 are Russian, 1 is Latin, 4 are French, 2 are German and 36 are in English.

TITLE:

On the Formation of the Tengizskaya and Karagandinskaya
Depressions (K formirovaniyu Tengizskoy i Karagandinskoy vpadin)

PERIODICAL:

Doklady Akademii nauk SSSR, 1959, Vol 126, Nr 3,
pp 630-633 (USSR)

ABSTRACT:

The geological structure of the depressions mentioned in the title (Central Kazakhstan) was described by N. G. Kassin, N. S. Shatskiy, D. G. Sapozhnikov, G. L. Kushev and in the references 1-6 et al. In spite of this, there are contradictory interpretations of several basic problems of regional geology (Refs 3, 6). In the present paper, the authors describe their ideas of the main formation stages of the two mentioned depressions. Besides, they characterize, on the basis of their investigations, their recent structure in general. In this recent structural plan, both depressions represent depressions between mountains. On the whole, they show rounded outlines which are a little extended in the lateral sense. The boundaries of the Tengizskaya Depression are drawn on the basis of indications of the early Cambrian and of the

Card 1/3

On the Formation of the Tengizskaya and
Karagandinskaya Depressions

SOV/20-126-3-48/69

lower and middle Paleozoic periods; in the Karaganda Depression, rocks of the lower and middle Devonian system are used for this purpose. Both depressions are limited by folded zones and anticlinoria, respectively. In the east, the Karaganda Depression is not quite closed, and is continued by the so-called Ashchisuykaya basin. The said reliefs formed at different points of time by different rocks according to their thickness and composition. The intensity and character of dislocations, the occurrence of magmatic activity etc are also different for individual reliefs. They are described in detail (Refs 1, 5). The whole manifold complex of sedimentary, metamorphic and magmatic formations taking part in the building-up of the two depressions and their surroundings, forms 3 distinctly from each other differing structural layers. They represent the main epochs of geotectonic evolution in the area referred to: the Caledonian folding epoch, the Hercynian Cycle of tectogenesis, and the Alpine folding (counted from bottom to top). During the Cretaceous and the Tertiary periods, the area referred to

Card 2/3

On the Formation of the Tengizskaya and
Karagandinskaya Depressions

SOV/20-126-3-48/69

was submitted to a denudation leveling owing to oscillating motions. Only at the end of the Oligocene, the wide and deep old valleys were filled with an accumulation of colored, mainly gypsum-containing loams due to a general lowering of the Central Kazakhstan. In the Quaternary period, the tendencies of a continuous lowering are partly maintained, and the recent structural plan is finally established. There are 6 Soviet references.
